

Transcript for Presentation

Welcome, everyone. Today, I'll walk you through this dashboard designed to provide insights into a telemarketing campaign's performance. The goal is to find the best model to sell long-term bank deposits.

Here, we start with a comparison of three statistical models: Classification Tree, Linear Regression, and Logistic Regression. While the accuracy for each model is high, they struggle with low recall, meaning potential leads could be missed. The classification tree, despite its limitations, currently offers the best balance of accuracy and other metrics like precision and recall. The benefit of this dashboard is to help the marketing team understand which model is currently the best and to compare the confusion matrix below using filter for different statistical models.

Next, we have a look at conversion rates based on customer characteristics. We notice that data has many unknown entries. Especially, the education chart shows that unknown has the highest conversion rate, which signals a data quality issue. This insight tells us to refine data collection methods, which will improve model performance and provide more accurate insights in the future.

This section focuses on prioritising sales efforts by identifying the best times and job categories for conversion. For instance, contacting students and retired individuals on Mondays or unemployed and housemaid on Wednesday. These insights guide the sales team in organising their schedules for maximum impact. In the future, we can expand

this analysis by gathering data on different time of the day to further optimise the outreach strategy.

Here, the dashboard shows how the number of contacts and successful outcomes fluctuate over time. A clear pattern creates where more calls tend to lead to better results. This highlights the importance of consistent customer engagement. We also see that longer call durations are correlated with higher conversion rates. This insight emphasises the value of investing time in more engaging conversations. The sales team can use this information to maintain momentum during slower periods. The future goal is to enhance these insights by integrating seasonality factors to identify high-potential months for campaigns.

Finally, we have a forecast graph showing conversion rate trends over the coming months. The data indicates that seasonal factors, such as the holiday period, contribute to higher conversion rates in March, October and December. The years over here are already in the past but we can double click any points to see upcoming holiday months as references. This information is particularly useful for the finance and marketing teams in planning future campaigns to align with these high-performing periods.

In summary, this dashboard serves as a strategic tool for understanding the telemarketing campaign's effectiveness. It provides actionable insights that empower the sales and marketing teams to target the right customers at the right time and improve overall performance. Going forward, expenses could be another main factor to consider for prediction. This will predict the future campaign's profitability.

Thank you for your attention. I'm happy to take any questions.
